## A.7 Errors and the Algebra of Calculus

### What you should learn
- Avoid common algebraic errors.
- Recognize and use algebraic techniques that are common in calculus.

### Why you should learn it
An efficient command of algebra is critical in mastering this course and in the study of calculus.

### Algebraic Errors to Avoid
This section contains five lists of common algebraic errors: errors involving parentheses, errors involving fractions, errors involving exponents, errors involving radicals, and errors involving dividing out. Many of these errors are made because they seem to be the easiest things to do. For instance, the operations of subtraction and division are often believed to be commutative and associative. The following examples illustrate the fact that subtraction and division are neither commutative nor associative.

#### Not commutative
- $4 - 3 \neq 3 - 4$
- $15 \div 5 \neq 5 \div 15$

#### Not associative
- $8 - (6 - 2) \neq (8 - 6) - 2$
- $20 \div (4 \div 2) \neq (20 \div 4) \div 2$

Appendix A.7 Errors and the Algebra of Calculus

A good way to avoid errors is to work slowly, write neatly, and talk to yourself. Each time you write a step, ask yourself why the step is algebraically legitimate. You can justify the step below because dividing the numerator and denominator by the same nonzero number produces an equivalent fraction.

\[ \frac{2x}{6} = \frac{2 \cdot x}{2 \cdot 3} = \frac{x}{3} \]

**Example 1** Using the Property for Adding Fractions

Describe and correct the error.

\[ \frac{1}{2x} + \frac{1}{3x} + \frac{1}{5x} \]

**Solution**

When adding fractions, use the property for adding fractions: \( \frac{1}{a} + \frac{1}{b} = \frac{b + a}{ab} \).

\[ \frac{1}{2x} + \frac{1}{3x} = \frac{3x + 2x}{6x^2} = \frac{5x}{6x^2} = \frac{5}{6x} \]

Now try Exercise 17.
Some Algebra of Calculus

In calculus it is often necessary to take a simplified algebraic expression and “unsimplify” it. See the following lists, taken from a standard calculus text.

The next five examples demonstrate many of the steps in the preceding lists.

**Example 2** Factors Involving Negative Exponents

Factor \(x(x + 1)^{-1/2} + (x + 1)^{1/2}\).

**Solution**

When multiplying factors with like bases, you add exponents. When factoring, you are undoing multiplication, and so you **subtract** exponents.

\[
x(x + 1)^{-1/2} + (x + 1)^{1/2} = (x + 1)^{-1/2}[x(x + 1)^0 + (x + 1)^1]
\]

\[
= (x + 1)^{-1/2}[x + (x + 1)]
\]

\[
= (x + 1)^{-1/2}(2x + 1)
\]

**CHECKPOINT** Now try Exercise 23.

Another way to simplify the expression in Example 2 is to multiply the expression by a fractional form of 1 and then use the Distributive Property.

\[
x(x + 1)^{-1/2} + (x + 1)^{1/2} = \left[ x(x + 1)^{-1/2} + (x + 1)^{1/2} \right] \cdot \frac{(x + 1)^{1/2}}{(x + 1)^{1/2}}
\]

\[
= \frac{x(x + 1)^0 + (x + 1)^1}{(x + 1)^{1/2}} = \frac{2x + 1}{\sqrt{x + 1}}
\]

**Example 3** Inserting Factors in an Expression

Insert the required factor: \(\frac{x + 2}{(x^2 + 4x - 3)^2} = (\ )\frac{1}{(x^2 + 4x - 3)^{2}}(2x + 4)\).

**Solution**

The expression on the right side of the equation is twice the expression on the left side. To make both sides equal, insert a factor of \(\frac{1}{2}\).

\[
\frac{x + 2}{(x^2 + 4x - 3)^2} = \left(\frac{1}{2}\right)\frac{1}{(x^2 + 4x - 3)^{2}}(2x + 4)
\]

**CHECKPOINT** Now try Exercise 25.
**Example 4**  **Rewriting Fractions**

Explain why the two expressions are equivalent.

\[
\frac{4x^2}{9} - 4y^2 = \frac{x^2}{9} - \frac{y^2}{4}
\]

**Solution**

To write the expression on the left side of the equation in the form given on the right side, multiply the numerators and denominators of both terms by \(\frac{1}{4}\).

\[
\frac{4x^2}{9} - 4y^2 = \frac{4x^2}{9} \left(\frac{1}{4}\right) - 4y^2 \left(\frac{1}{4}\right) = \frac{x^2}{9} - \frac{y^2}{4}
\]

**Example 5**  **Rewriting with Negative Exponents**

Rewrite each expression using negative exponents.

a. \(\frac{-4x}{(1 - 2x^2)^2}\)  
b. \(\frac{2}{5x^3} - \frac{1}{\sqrt{x} + \frac{3}{5(4x)^2}}\)

**Solution**

a. \(\frac{-4x}{(1 - 2x^2)^2} = -4x(1 - 2x^2)^{-2}\)

b. Begin by writing the second term in exponential form.

\[
\frac{2}{5x^3} - \frac{1}{\sqrt{x} + \frac{3}{5(4x)^2}} = \frac{2}{5x^3} - \frac{1}{x^{1/2} + \frac{3}{5(4x)^2}}
\]

\[
= \frac{2}{5x^3} - x^{-1/2} + \frac{3}{5(4x)^{-2}}
\]

**Example 6**  **Writing a Fraction as a Sum of Terms**

Rewrite each fraction as the sum of three terms.

a. \(\frac{x^2 - 4x + 8}{2x}\)  
b. \(\frac{x + 2x^2 + 1}{\sqrt{x}}\)

**Solution**

a. \(\frac{x^2 - 4x + 8}{2x} = \frac{x^2 - 4x}{2x} + \frac{8}{2x}\)

\[= \frac{x}{2} - 2 + \frac{4}{x}\]

b. \(\frac{x + 2x^2 + 1}{\sqrt{x}} = \frac{x}{\sqrt{x}^{3/2}} + \frac{2x^2}{\sqrt{x}} + \frac{1}{\sqrt{x}}\)

\[= x^{1/2} + 2x^{3/2} + x^{-1/2}\]

**CHECKPOINT**  Now try Exercise 29.

**CHECKPOINT**  Now try Exercise 39.

**CHECKPOINT**  Now try Exercise 43.
